(54) Surface acoustic wave filter and communications apparatus

(57) A SAW filter includes a plurality of IDTs (204-6) along a SAW propagation direction, and balanced signal terminals (210, 211) connected to an IDT. Then, the SAW filter is of a floating balanced type. The plurality of IDTs (204-206) are set so as to provide a horizontally asymmetrical structure with respect to an imaginary axis

(222) that is positioned at the center of the center IDT in the SAW propagation direction and which is orthogonal to the SAW propagation direction. Thus, a SAW filter having filtering characteristics and a balance-to-unbalance conversion function is achieved with high balance between the balanced signal terminals.

FIG. 1

Description

BACKGROUND OF THE INVENTION

1. Field of the Invention

[0001] The present invention relates to a surface acoustic wave filter having filtering characteristics and, in particular, a balance-to-unbalance conversion function, and to a communications apparatus using the surface acoustic wave filter.

2. Description of the Related Art

[0002] Recently, there has been significant technological progress in reducing the size and weight of cellular telephones. In order to achieve this, in addition to reducing the number and size of components, multi-function components are being increasingly developed. In the state of the art, recent research has been actively conducted on surface acoustic wave (SAW) filters having a balance-to-unbalance conversion function, i.e., a so-called "balun" function, which are used in the RF (radio frequency) stage of cellular telephones. Such SAW filters are used mostly for GSM (global system for mobile communications) compliant devices.

[0003] If a balanced line such as a twin lead feeder is directly coupled to an unbalanced line such as a coaxial cable, an unbalanced current flows, thereby, undesirably, causing the feeder itself to operate as an antenna. A circuit called a balun is thus required for preventing the unbalanced current in order to match the balanced line to the unbalanced line.

[0004] Many patent applications pertaining to SAW filters having a balance-to-unbalance conversion function have been filed. A well-known SAW filter having a balance-to-unbalance conversion function and whose input impedance and output impedance are substantially equal is illustrated in Fig. 19.

[0005] In the SAW filter shown in Fig. 19, a comb-like electrode (also called an interdigital transducer, hereinafter referred to as an "IDT") 101 is formed on a piezoelectric substrate 100. IDTs 102 and 103 are positioned on the left and right sides of the IDT 101, respectively, in the surface acoustic wave (SAW) propagation direction.

[0006] Reflectors 104 and 105 for reflecting a surface acoustic wave in order to improve the conversion efficiency are further arranged in the SAW filter in such a manner that they sandwich the IDTs 101, 102, and 103 therebetween from the left and right. The SAW filter further includes balanced signal terminals 106 and 107, and an unbalanced signal terminal 108.

[0007] The SAW filter of this type is called a three-IDT longitudinally coupled resonator SAW filter having a balance-to-unbalance conversion function by performing conversion between the IDTs 101, 102, and 103 using a surface acoustic wave.

[0008] In a SAW filter having a balance-to-unbalance conversion function, it is required that the transmission characteristics in the pass band between an unbalanced signal terminal and each balanced signal terminal have equal amplitude characteristics and 180°-out-of-phase characteristics. The extent to which the amplitude characteristic and the phase characteristic meet these requirements is assessed in terms of "amplitude balance" and "phase balance" between the balanced signal terminals, respectively.

[0009] The amplitude balance and the phase balance are defined as follows. If the SAW filter having a balance-to-unbalance conversion function is a three-port device consisting of, for example, a first port corresponding to an unbalanced input terminal and second and third ports corresponding to balanced output terminals, the amplitude balance = A , where $A = 10 \log(S_{21} / |S_{21}|)$, and the phase balance = $B - 180$, where $B = \angle S_{21} - \angle S_{31}$. In the above equations, S_{21} denotes the transfer coefficient from the first port to the second port, S_{31} denotes the transfer coefficient from the first port to the third port, and $| \cdot |$ indicates an absolute value.

[0010] In balance between the balanced signal terminals, ideally, the amplitude balance and the phase balance are 0 dB and 0 degree, respectively, in the pass band of a SAW filter.

[0011] However, the SAW filter in the conventional art shown in Fig. 19 has a problem in that balance between the balanced signal terminals is low. As one possible reason, the distance (indicated by a portion 109 in Fig. 19) between an electrode finger connected to the balanced signal terminal 106 and a signal electrode finger of the IDT 102 is different from the distance (indicated by a portion 110 in Fig. 19) between an electrode finger connected to the balanced signal terminal 107 and a signal electrode finger of the IDT 103 by 0.5 times the wavelength defined by the pitch between the electrode fingers.

[0012] This leads to additional problems in that the total capacitance of the electrode fingers connected to the balanced signal terminal 106 is different from that of the electrode fingers connected to the balanced signal terminal 107, and that the conversion efficiency between an electrical signal and a surface acoustic wave is different between the balanced signal terminals 106 and 107, resulting in low balance. Fig. 20 shows that the balanced signal terminal 107 shown in Fig. 19 is connected to the ground, and Fig. 21 shows that the balanced signal terminal 106 shown in Fig. 19 is connected to the ground. Fig. 22 shows the difference between the frequency-amplitude characteristic output from the balanced signal terminal 106 in Fig. 20 (represented by a solid line in Fig. 22) and the frequency-amplitude characteristic output from the balanced signal terminal 107 in Fig. 21 (represented by a dot-chain line in Fig. 22). There is a large difference between the two amplitude characteristics, and this difference introduces low balance.

SUMMARY OF THE INVENTION

[0013] Accordingly, it is an object of the present invention to provide a surface acoustic wave filter having a balance-to-unbalance conversion function that compensates for the above-described difference between balanced signal terminals, which is one reason for low balance between the balanced signal terminals, and that exhibits satisfactory balance between the balanced signal terminals, and to provide a communications apparatus using the SAW filter.

[0014] To this end, in an aspect of the present invention, a SAW filter includes a piezoelectric substrate, an interdigital transducer (IDT) set formed on the piezoelectric substrate, and a balanced signal terminal connected to the IDT set. The IDT set includes, along a SAW propagation direction, a plurality of IDTs for converting an input electrical signal into a surface acoustic wave and outputting the surface acoustic wave, and for converting a propagating surface acoustic wave into an output electrical signal and outputting the output electrical signal. The IDT set is asymmetric with respect to an imaginary axis which is located at the center of the IDT set in the SAW propagation direction and which is orthogonal to the SAW propagation direction.

[0015] The IDT set may include an odd number of IDTs. The imaginary axis may be located at central portion of the IDT which is centrally located among the plurality of the IDTs, and may be orthogonal to the SAW propagation direction.

[0016] The distances between adjacent IDTs in the IDT set may be different such that the interdigital transducer set is asymmetric with respect to the imaginary axis.

[0017] The duty ratios of the electrode finger widths to the pitches of the IDT set may be different such that the interdigital transducer set is asymmetric with respect to the imaginary axis.

[0018] The pitches of the interdigital transducer set may be different such that the interdigital transducer set is asymmetric with respect to the imaginary axis.

[0019] The IDT set may include narrower-pitch electrode finger portions at portions where two IDTs are adjacent to each other, each narrower-pitch electrode finger portion including several electrode fingers having a smaller pitch than that of the other electrode fingers. The pitches of the narrower-pitch electrode finger portions may be different such that the interdigital transducer set is asymmetric with respect to the imaginary axis.

[0020] With this configuration, the IDT set having a plurality of IDTs in the SAW propagation direction can achieve a filtering function which allows specific frequency band components to pass while other components to be prevented.

[0021] In this configuration, a balanced signal terminal connected to the IDT set does not have an electrically neutral point and therefore is of a floating balanced type, thus implementing a balance-to-unbalance con-

version function while making it possible to relatively readily set an imaginary axis that is positioned at the center of the IDT set in the SAW propagation direction and which is orthogonal to the propagation direction.

[0022] In this configuration, the IDT set is configured so as to be asymmetric with respect to the imaginary axis. For example, the distances between adjacent IDTs may be asymmetric with respect to the imaginary axis, the duty ratios of the IDT set may be asymmetric with respect to the imaginary axis, and/or the narrower-pitch electrode finger portions provided on the IDT set may be asymmetric with respect to the imaginary axis. This increases balance, in particular, the phase balance.

[0023] Accordingly, a SAW filter implementing both a filtering function and a balance-to-unbalance conversion function in which balance, in particular, the phase balance, is improved can be achieved, and can also be suitably used for communications apparatuses such as cellular telephones.

[0024] In the SAW filter, preferably, at least one SAW resonator is connected at least in series or in parallel to the IDT set. The SAW resonator connected to the IDT set increases the filtering function.

[0025] In another aspect of the present invention, a communications apparatus includes a surface acoustic wave filter having any of the foregoing configuration. With use of a surface acoustic wave filter implementing both a filtering function and a balance-to-unbalance conversion function in which balance, in particular, the phase balance, is improved, the communications capability can be improved.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

[0027] Embodiments of the present invention are now described with reference to Figs. 1 to 19.

First Embodiment

[0028] In a SAW filter according to a first embodiment of the present invention, as shown in Fig. 1, on a piezoelectric substrate 20, a longitudinally coupled resonator SAW filter unit (IDT set) 201, and SAW resonators 202 and 203 connected in series to the SAW filter unit 201 are formed of an aluminum (Al) electrode (foil) produced by a technique such as photolithography. The piezoelectric substrate 20 may be a 40±15° Y-cut X-propagating

LiTaO₃ substrate. The following embodiments of the present invention are described in the context of a PCS (personal communication system) reception SAW filter.

[0029] The SAW filter unit 201 includes an IDT 205, and IDTs 204 and 206, which sandwich the IDT 205 therebetween from the left and right in the SAW propagation direction. The SAW filter unit 201 further includes reflectors 207 and 208 positioned beside the IDTs 204 and 206, respectively.

[0030] The IDTs 204, 205, and 206 each have two electrode finger portions each including a strip base portion (bus bar) and a plurality of strip electrode fingers extending in parallel to each other and extending orthogonally from one side of the base portion. The electrode finger portions are configured so that the electrode fingers of one electrode finger portion are interleaved with the electrode fingers of the other electrode finger portion such that the sides thereof face each other.

[0031] In any of the IDTs 204, 205, and 206, if a potential difference occurs due to electrical signals input to the two electrode finger portions via the base portions (bus bars), a surface acoustic wave is produced at that portion on a surface of the piezoelectric substrate 20. The surface acoustic wave then propagates across the surface of the piezoelectric substrate 20 in a bi-directional manner in the width direction of the electrode fingers, i.e., in the direction orthogonal to the length of the electrode fingers. In an IDT to which no electrical signal is input, the potential difference produced on the surface of the piezoelectric substrate 20 by the propagating surface acoustic wave is detected by the electrode fingers, and is converted into an output electrical signal, which is then output.

[0032] In the IDTs 204, 205, and 206, the signal conversion characteristic or the pass band can be determined by setting the length and width of each electrode finger, the pitch between adjacent electrode fingers, and the interdigital length which means the length by which the interleaved electrode fingers face each other. The reflectors 207 and 208 reflect a propagating surface acoustic wave.

[0033] As is apparent from Fig. 1, in the SAW filter unit 201, the pitch between some electrode fingers (narrower-pitch electrode fingers) near the portion (indicated by a portion 213) where the adjacent IDTs 204 and 205 face each other is smaller than the pitch between the other electrode fingers of the IDTs 204 and 205. Likewise, the pitch between some electrode fingers (narrower-pitch electrode fingers) near the portion (indicated by a portion 214) where the adjacent IDTs 205 and 206 face each other is narrower than the pitch between the other electrode fingers of the IDTs 205 and 206. Thus, the insertion loss in the SAW filter unit 201 can be reduced.

[0034] Balanced signal terminals 210 and 211 are connected to the electrode finger portions of the center IDT 205. Then, the SAW filter unit 201 does not have a ground potential as an electrically neutral point, and therefore is of the floating balanced type. An unbalanced

signal terminal 209 is connected to one electrode finger portion in each of the IDTs 204 and 206. The other electrode finger portion in each of the IDTs 204 and 206 is connected to the ground.

[0035] Connecting the balanced signal terminals 210 and 211 and the unbalanced signal terminal 209 in this manner can provide a balance-to-unbalance conversion function for the SAW filter unit 201. Specifically, when a balanced electrical signal is input to the balanced signal terminals 210 and 211, an unbalanced electrical signal is output from the unbalanced signal terminal 209. On the other hand, when an unbalanced electrical signal is input to the unbalanced signal terminal 209, a balanced electrical signal is output from the balanced signal terminals 210 and 211.

[0036] The SAW resonators 202 and 203 are connected in series between the unbalanced signal terminal 209 and the IDTs 204 and 206 via a signal line 212. For simplicity of illustration, the number of electrode fingers shown in Fig. 1 is less than actually provided.

[0037] A ground line 221 is disposed between the signal line 212 and the balanced signal terminal 210, which carries a shield pattern for reducing the bridge capacitance therebetween.

[0038] In the SAW filter according to the first embodiment, the IDTs 204, 205, and 206 are set so that the pitch between the IDTs 204 and 205, which are adjacent to each other in the SAW propagation direction, is different from the pitch between the IDTs 205 and 206, which are adjacent to each other in the SAW propagation direction. In other words, the SAW filter according to the first embodiment has a horizontally asymmetrical structure with respect to an imaginary axis 222 that is positioned at the center of the center IDT 205 in the SAW filter unit 201 in the SAW propagation direction and which is orthogonal to the SAW propagation direction.

[0039] Where the wavelength defined by the pitch between the narrower-pitch electrode fingers is indicated by λ_2 (indicated by the portions 213 and 214 in Fig. 1), and the wavelength defined by the pitch between the other electrode fingers is indicated by λ_1 , the specific design of the longitudinally coupled resonator SAW filter unit 201 is as follows:

interdigital length W: $60.6 \lambda_1$;
 number of electrode fingers of the IDT 204: 29(4)
 number of electrode fingers of the IDT 205: 4(4)5(4)
 number of electrode fingers of the IDT 206: 4(4)29

(the number in parentheses indicates the number of narrower-pitch electrode fingers);

IDT wavelength λ_1 : $2.06 \mu\text{m}$
 λ_2 : $1.88 \mu\text{m}$;
 reflector wavelength λ_R : $2.07 \mu\text{m}$;
 number of electrode fingers of reflector: 100;
 pitch between the IDTs 204 and 205: $0.500 \lambda_2$ (indicated by a portion 219 in Fig. 1)

pitch between the IDTs 205 and 206: $0.484 \lambda_2$ (indicated by a portion 220 in Fig. 1);
 pitch between electrode finger having wavelength λ_1 and electrode finger having wavelength λ_2 (indicated by portions 215, 216, 217, and 218 in Fig. 1): $0.250 \lambda_1 + 0.250 \lambda_2$;
 pitch between IDT and reflector: $0.470 \lambda_R$
 duty ratio: 0.60 (for IDT and reflector); and
 electrode thickness: $0.080 \lambda_1$.

[0040] The specific design of the SAW resonator 202 is as follows:

interdigital length W: 49.1λ ;
 number of electrode fingers of IDT: 401;
 wavelength λ (for IDT and reflector): $2.04 \mu\text{m}$;
 number of electrode fingers of reflector: 30;
 pitch between IDT and reflector: 0.50λ ;
 duty ratio: 0.60 (for IDT and reflector); and
 electrode thickness: 0.080λ .

[0041] The specific design of the SAW resonator 203 is as follows:

interdigital length W: 40.6λ ;
 number of electrode fingers of IDT: 241;
 wavelength λ (for IDT and reflector): $1.97 \mu\text{m}$;
 number of electrode fingers of reflector: 30;
 pitch between IDT and reflector: 0.50λ ;
 duty ratio: 0.60 (for IDT and reflector); and
 electrode thickness: 0.084λ .

[0042] As used herein, "pitch" means the center-to-center distance between two electrode fingers in the width direction thereof.

[0043] Figs. 2 and 3 are graphs showing the amplitude balance and the phase balance between the balanced signal terminals, respectively, in the frequency characteristic of the SAW filter according to the first embodiment. A SAW filter in a comparative example shown in Fig. 4 uses a SAW filter unit 201a in which the pitch between the IDTs 204 and 205 is the same as the pitch between the IDTs 205 and 206. The amplitude balance and the phase balance of the SAW filter in the comparative example are also shown in Figs. 2 and 3.

[0044] The SAW filter in the comparative example shown in Fig. 4 has the same structure as the SAW filter in the first embodiment, except that the pitch between the IDTs 204 and 205 is the same as the pitch between the IDTs 205 and 206. Although not shown in Fig. 4, the piezoelectric substrate 20 is used in the SAW filter in the comparative example.

[0045] The frequency of the pass band of a PCS reception filter ranges from 1930 MHz to 1990 MHz. The amplitude balance in this frequency range is -0.75 to +2.30 dB (having a deviation of 3.05 dB) for the comparative example, while it is -0.80 to +2.30 dB (having a deviation of 3.10 dB) for the first embodiment. The

phase balance is -7.0 to $+5.5^\circ$ (having a deviation of 12.5°) for the comparative example, while it is -4.0 to $+5.5^\circ$ (having a deviation of 9.5°) for the first embodiment. The smaller the deviation, the higher the amplitude balance, and the smaller the deviation, the higher the phase balance. In the first embodiment, therefore, the amplitude balance is slightly lower, while the phase balance is about 3.0° higher.

[0046] This is an advantage achieved by making the pitch between the IDTs 204 and 205 different from the pitch between the IDTs 205 and 206 to compensate for a difference between the total capacitance of the electrode fingers connected to the balanced signal terminal 210 and the total capacitance of the electrode fingers connected to the balanced signal terminal 211, and for a difference in conversion efficiency between an electrical signal and a surface acoustic wave between the balanced signal terminals 210 and 211. Figs. 5 and 6 show the transmission characteristics of the SAW filter in the comparative example and the SAW filter in the first embodiment, respectively. The transmission characteristic for the first embodiment is substantially the same as that for the comparative example, although the transmission characteristic for the first embodiment exhibits a small undesirable ripple A in the pass band, as shown in Fig. 6.

[0047] If the pitches between IDTs on the left and right sides of the SAW filter unit 201 greatly differ, a large undesirable ripple A is exhibited in the pass band. Therefore, the pitches between IDTs should be adjusted so that the undesirable ripple is not large and, preferably, the ripple does not exceed 1.0 dB, which is a commercial requirement of the deviation in the pass band, in order to achieve the advantage of the first embodiment.

[0048] According to the first embodiment, therefore, the SAW filter having a balance-to-unbalance conversion function is configured so that the pitches between IDTs on the left and right sides are different so as to provide a horizontally asymmetrical structure with respect to the imaginary axis 222 that is positioned at the center of the center IDT 205 of the SAW filter unit 201 and which is orthogonal to the SAW propagation direction. Consequently, the SAW filter according to the first embodiment can have a higher phase balance between balanced signal terminals than the SAW filter in the comparative example.

[0049] In the first embodiment, a single longitudinally coupled resonator SAW filter unit 201 having three IDTs 204, 205, and 206 is used, and two SAW resonators 202 and 203 are connected in series to the SAW filter unit 201, in which a balanced signal is obtained from the center IDT 205 of the longitudinally coupled resonator SAW filter unit 201. However, the present invention is not limited to this form, and a SAW filter having balanced signal terminals of any configuration can achieve advantages similar to those of the first embodiment.

[0050] For example, in a longitudinally coupled resonator SAW filter having four IDTs, as shown in Fig. 7, a pitch 301 between adjacent IDTs is different from a pitch

302 between adjacent IDTs so as to provide a horizontally asymmetrical structure with respect to an imaginary axis 303 that is positioned at the center of the SAW filter unit and which is orthogonal to the SAW propagation direction. With the horizontally asymmetrical structure, advantages similar to those in the first embodiment can be achieved.

[0051] It is apparent that advantages similar to those of the first embodiment are achieved by a SAW filter having more IDTs. For example, a SAW filter having a SAW resonator connected in parallel to the SAW filter unit 201 may be used. As shown in Fig. 8, a SAW filter may be configured such that the unbalanced signal terminal 209 is input (output) from the opposite sides of IDTs 304 and 306 of the longitudinally coupled resonator SAW filter unit. A SAW filter having two longitudinally coupled resonator SAW filter units connected in a cascade manner may be used. These SAW filters would achieve advantages similar to those of the first embodiment if, for example, in Fig. 8, the SAW filter has a horizontally asymmetrical structure with respect to an imaginary axis 322.

[0052] In the SAW filter according to the first embodiment, the piezoelectric substrate 20 is a $40 \pm 5^\circ$ Y-cut X-propagating LiTaO_3 substrate; however, the present invention is not limited thereto, as anticipated from the principle that the advantages of the present invention are achieved. The piezoelectric substrate 20 may be made of 64° to 72° Y-cut X-propagating LiNbO_3 , 41° Y-cut X-propagating LiNbO_3 , or the like.

Second Embodiment

[0053] Fig. 9 shows a SAW filter according to a second embodiment of the present invention. The SAW filter according to the second embodiment is different from that in the comparative example shown in Fig. 4 in that the duty ratio of the electrode fingers of the IDT 402 that are connected to the unbalanced signal terminal 409 is changed from 0.60 to 0.50 . Given that an imaginary axis 420 is positioned at the center of the center IDT 403 of a SAW filter unit 401, and is orthogonal to the SAW propagation direction, the SAW filter unit 401 has a horizontally asymmetrical structure with respect to the imaginary axis 420. The structure of the other components is the same as that of the comparative example.

[0054] Figs. 10 and 11 are graphs showing the amplitude balance and the phase balance between balanced signal terminals 410 and 411, respectively, in the frequency characteristic of the SAW filter according to the second embodiment. For comparison, the amplitude balance and the phase balance of the SAW filter in the comparative example shown in Fig. 4 are also shown in Figs. 10 and 11, respectively.

[0055] In the SAW filter in the second embodiment, the duty ratio of the electrode fingers of the IDT 402 that are connected to the unbalanced signal terminal 409 is changed, thus making the bandpass frequency band about 1 MHz higher than that of the SAW filter in the

comparative example.

[0056] For simplification of comparison between the second embodiment and the comparative example, in Figs. 10 and 11, the frequency of the SAW filter in the second embodiment is 1 MHz lower than actually provided. The amplitude balance in the frequency range of the pass band of a PCS reception filter is -0.75 dB to +2.30 dB (having a deviation of 3.05 dB) for the comparative example, while it is -0.75 dB to +2.25 dB (having a deviation of 3.00 dB) for the second embodiment. In the second embodiment, therefore, the amplitude balance is about 0.05 dB higher.

[0057] The phase balance in the frequency range is -7.0° to $+5.5^\circ$ (having a deviation of 12.5°) for the comparative example, while it is -4.5° to $+5.0^\circ$ (having a deviation of 9.5°) for the second embodiment. In the second embodiment, therefore, the phase balance is about 3.0° higher. This is an advantage achieved by reducing the duty ratio of the electrode fingers of the IDT 402 that are connected to the unbalanced signal terminal 409 to compensate for a difference between the total capacitance of the electrode fingers connected to the balanced signal terminal 410 and the total capacitance of the electrode fingers connected to the balanced signal terminal 411, and for a difference in conversion efficiency between an electrical signal and a surface acoustic wave between the balanced signal terminals 410 and 411. The SAW filter in the second embodiment exhibits substantially the same transmission characteristic in the pass band as the SAW filter in the comparative example, as is apparent from Fig. 5 showing the transmission characteristic for the comparative example and Fig. 12 showing the transmission characteristic for the second embodiment.

[0058] According to the second embodiment, therefore, the SAW filter having a balance-to-unbalance conversion function is configured so that the duty ratio of the electrode fingers of the IDT 402 that are connected to the unbalanced signal terminal 409 is reduced so as to provide a horizontally asymmetrical structure with respect to the imaginary axis 420 that is positioned at the center of the center IDT 403 of the SAW filter unit 401 and which is orthogonal to the SAW propagation direction. Consequently, the SAW filter according to the second embodiment can have higher balance between the balanced signal terminals 410 and 411 than the SAW filter in the comparative example.

[0059] In the second embodiment, only the duty ratio of a signal electrode is changed; however, the duty ratio of either a signal electrode or a ground electrode may be changed to provide a horizontally asymmetrical structure, thereby achieving advantages similar to those of the second embodiment. Furthermore, while the duty ratio is reduced in the second embodiment, the duty ratio of, for example, the IDT 404 may be increased, thereby providing higher balance. The duty ratio may be increased or reduced depending upon the IDTs.

Third Embodiment

[0060] A SAW filter according to a third embodiment of the present invention is now described with reference to Fig. 13. The SAW filter according to the third embodiment is the same as the SAW filter in the comparative example shown in Fig. 4, except that a SAW filter unit 201b having an IDT 204a whose pitch is $0.01\text{ }\mu\text{m}$ smaller than the pitch of the IDT 204 in Fig. 4. Thus, the SAW filter unit 201b has a horizontally asymmetrical structure with respect to an imaginary axis that is positioned at the center of the center IDT 205 of the SAW filter unit 201b and which is orthogonal to the SAW propagation direction.

[0061] Figs. 14 and 15 are graphs showing the amplitude balance and the phase balance between balanced signal terminals, respectively, in the frequency characteristic of the SAW filter according to the third embodiment. For comparison, the amplitude balance and the phase balance of the SAW filter in the comparative example shown in Fig. 4 are also shown in Figs. 14 and 15, respectively.

[0062] In the third embodiment, the IDT 204a whose pitch is $0.01\text{ }\mu\text{m}$ smaller than the pitch of the IDT 204 in Fig. 4 is used, thus making the bandpass frequency about 1 MHz higher than that of the SAW filter in the comparative example. For simplification of comparison between the third embodiment and the comparative example, in Figs. 14 and 15, the frequency of the SAW filter in the third embodiment is 1 MHz lower than actually provided.

[0063] The amplitude balance in the frequency range of the pass band of a PCS reception SAW filter is -0.75 dB to +2.30 dB (having a deviation of 3.05 dB) for the comparative example, while it is -0.75 dB to +2.40 dB (having a deviation of 3.15 dB) for the third embodiment. The phase balance is -7.0° to $+5.5^\circ$ (having a deviation of 12.5°) for the comparative example, while it is -3.5° to $+6.0^\circ$ (having a deviation of 9.5°) for the third embodiment. In the third embodiment, therefore, the amplitude balance is slightly lower, although the phase balance is about 3.0° higher.

[0064] This is an advantage achieved by using the IDT 204a whose pitch is smaller than that of the IDT 204 to compensate for a difference between the total capacitance of the electrode fingers connected to the balanced signal terminal 210 and the total capacitance of the electrode fingers connected to the balanced signal terminal 211, and for a difference in conversion efficiency between an electrical signal and a surface acoustic wave between the balanced signal terminals 210 and 211.

[0065] The SAW filter in the third embodiment exhibits substantially the same transmission characteristic in the pass band as the SAW filter in the comparative example, although the pass bandwidth is slightly narrower than that in the comparative example, as is apparent from Fig. 5 showing the transmission characteristic for the

comparative example and Fig. 16 showing the transmission characteristic for the third embodiment.

[0066] According to the third embodiment, therefore, the SAW filter having a balance-to-unbalance conversion function is configured so that the IDT 204a whose pitch is smaller than the pitch of the IDT 204 in the comparative example is used so as to provide a horizontally asymmetrical structure with respect to an imaginary axis that is positioned at the center of the center IDT 205 of the SAW filter unit 201b and which is orthogonal to the SAW propagation direction. Consequently, the SAW filter according to the third embodiment can have a higher phase balance between the balanced signal terminals 210 and 211 than the SAW filter in the comparative example.

[0067] While the pitch is reduced in the third embodiment, the pitch of, for example, the IDT 206 may be increased, thereby providing higher balance. The pitch may be increased or reduced depending upon the IDTs.

[0068] Furthermore, the pitch between narrower-pitch electrode fingers near the portion where the IDTs 204 and 205 are adjacent to each other may be different from the pitch between narrower-pitch electrode fingers near the portion where the IDTs 205 and 206 are adjacent to each other, as shown in Fig. 17. For example, the SAW filter shown in Fig. 17 is the same as the SAW filter in the comparative example shown in Fig. 4, except that it uses a SAW filter unit 201c having an IDT 204b in which the pitch between narrower-pitch electrode fingers is smaller than the pitch between narrower-pitch electrode fingers in the IDT 204 shown in Fig. 4, and an IDT 205a in which the pitch between narrower-pitch electrode fingers near the IDT 204b is smaller than the pitch between narrower-pitch electrode fingers in the IDT 205 near the IDT 204 shown in Fig. 4.

[0069] Accordingly, in the configuration shown in Fig. 17, the pitch between electrode fingers near the portion where the IDT 205a is adjacent to the IDT 204b and the pitch between electrode fingers near the portion where the IDT 205a is adjacent to the IDT 206 are horizontally asymmetric with respect to an imaginary axis that is positioned at the center of the center IDT 205a of the SAW filter unit 201c and which is orthogonal to the SAW propagation direction. Consequently, the SAW filter can have higher balance between the balanced signal terminals 210 and 211 than the SAW filter in the comparative example.

[0070] In a SAW filter according to the present invention, therefore, on a piezoelectric substrate, a plurality of IDTs are formed along the SAW propagation direction, and balanced signal input terminals or balanced signal output terminals are formed. The surface acoustic wave filter does not have an electrically neutral point, and therefore is of the floating balanced type. The surface acoustic wave filter has a horizontally asymmetrical structure with respect to an imaginary axis that is positioned at the center IDT of the SAW filter and which is orthogonal to the SAW propagation direction. With the

horizontally asymmetrical structure, the SAW filter can have higher balance (the phase balance, in particular) between the balanced signal terminals.

[0071] In a preferable form, the SAW filter has an odd number of IDTs, and has a horizontally asymmetrical structure with respect to an imaginary axis that is positioned at the center of the center IDT of the IDTs and which is orthogonal to the SAW propagation direction.

[0072] Preferable configurations or methods to provide a horizontally asymmetrical structure are as follows:

- (1) the distances between adjacent IDTs in the SAW filter are horizontally asymmetric with respect to the imaginary axis orthogonal to the SAW propagation direction;
- (2) the duty ratios of a plurality of IDTs in the SAW filter are horizontally asymmetric with respect to the imaginary axis orthogonal to the SAW propagation direction;
- (3) the pitches of a plurality of IDTs in the SAW filter are horizontally asymmetric with respect to the imaginary axis orthogonal to the SAW propagation direction; and
- (4) the SAW filter includes narrower-pitch electrode finger portions in which the pitch between several electrode fingers is smaller than the pitch between the other electrode fingers at the portion where two IDTs are adjacent to each other, wherein the pitches of the narrower-pitch electrode finger portions are horizontally asymmetric with respect to the imaginary axis orthogonal to the SAW propagation direction.

[0073] The SAW filter according to the present invention preferably includes at least one SAW resonator connected in series or in parallel or in combination thereof in order to increase the out-of-passband attenuation.

[0074] Although the features of the first to third embodiments have been separately illustrated, by way of example, in the foregoing description, it is apparent that advantages similar to those of the embodiments can be obtained by using any combination of these embodiments.

[0075] A description is now given, with reference to Fig. 18, of a communications apparatus 600 using a SAW filter according to any of the first to third embodiments. In the communications apparatus 600, a receiver (Rx) for reception includes an antenna 601, an antenna duplexer/RF top filter 602, an amplifier 603, Rx inter-stage filter 604, a mixer 605, a first IF filter 606, a mixer 607, a second IF filter 608, a first-and-second signal local synthesizer 611, a temperature compensated crystal oscillator (TCXO) 612, a divider 613, and a local filter 614.

[0076] Preferably, two balanced signals are transmitted from the Rx inter-stage filter 604 to the mixer 605, as indicated by two lines in Fig. 18, in order to maintain

balance.

[0077] In the communications apparatus 600, a transmitter (Tx) for transmission includes the antenna 601, the antenna duplexer/RF top filter 602, a Tx IF filter 621, a mixer 622, a Tx inter-stage filter 623, an amplifier 624, a coupler 625, an isolator 626, and an automatic power control (APC) 627. The antenna 601 and the antenna duplexer/RF top filter 602 are shared by the receiver and the transmitter.

[0078] The SAW filter according to any of the first to third embodiments may be suitably used as any or all of the Rx inter-stage filter 604, the first IF filter 606, the Tx IF filter 621, and the Tx inter-stage filter 623.

[0079] The SAW filter according to the present invention has both a filtering function and a balance-to-unbalance conversion function, and exhibits a satisfactory characteristic, i.e., an ideal phase characteristic between balanced signals. Therefore, a communications apparatus in the present invention, which uses such a SAW filter, has a higher transmission characteristic.

Claims

1. A surface acoustic wave filter comprising:
 - a piezoelectric substrate (20);
 - an interdigital transducer set (201) formed on the piezoelectric substrate (20), the interdigital transducer set (201) including, along a surface acoustic wave propagation direction, a plurality of interdigital transducers (204-6) for converting an input electrical signal into a surface acoustic wave and outputting the surface acoustic wave, and for converting a propagating surface acoustic wave into an output electrical signal and outputting the output electrical signal; and
 - a balanced signal terminal (210/211) connected to the interdigital transducer set (201),

wherein the interdigital transducer set (201) is asymmetric with respect to an imaginary axis (222) which is located at the center of the interdigital transducer set (201) in the surface acoustic wave propagation direction and which is orthogonal to the surface acoustic wave propagation direction.
2. A surface acoustic wave filter according to claim 1, wherein the interdigital transducer set (201) includes an odd number of interdigital transducers (204-6), and
 - the imaginary axis (222) is located at central portion of the interdigital transducer (205) which is centrally located among the plurality of the interdigital transducers, and is orthogonal to the surface acoustic wave propagation direction.
3. A surface acoustic wave filter according to claim 1 or 2, wherein the distances (219,220) between adjacent interdigital transducers in the interdigital transducer set (201) are different such that the interdigital transducer set is asymmetric with respect to the imaginary axis.
4. A surface acoustic wave filter according to claim 1, 2 or 3, wherein the ratios of the electrode finger widths to the pitches of the interdigital transducers (402,404) of the interdigital transducer set (401) are different such that the interdigital transducer set is asymmetric with respect to the imaginary axis.
5. A surface acoustic wave filter according to claim 1, 2, 3 or 4, wherein the pitches of the interdigital transducers (204a,206) of the interdigital transducer set are different such that the interdigital transducer set is asymmetric with respect to the imaginary axis.
6. A surface acoustic wave filter according to any previous claim, wherein the interdigital transducer set includes narrower-pitch electrode finger portions at portions (213,214) where two interdigital transducers are adjacent to each other, each narrower-pitch electrode finger portion including several electrode fingers having a smaller pitch than that of the other electrode fingers, and
 - the pitches of the narrower-pitch electrode finger portions are different such that the interdigital transducer set is asymmetric with respect to the imaginary axis.
7. A surface acoustic wave filter according to any previous claim, wherein at least one surface acoustic wave resonator (202/203) is connected at least in series or in parallel to the interdigital transducer set (201).
8. A communications apparatus (600) comprising the surface acoustic wave filter according to any previous claim.
